# Condensation of $\left.\left[R u_{3} \mathrm{~S}_{2} \text { (cymene) }\right)_{3}\right]^{2+}$ with Sulfide To Give the Dendridic Cluster $\left[R u_{9} S_{8} \text { (cymene) }\right]^{2+}$ 

Matthew L. Kuhlman and Thomas B. Rauchfuss*<br>Department of Chemistry, University of Illinois at Urbana-Champaign, Urbana, Illinois 61801

Received May 1, 2004

Summary: Reaction of $\left[(\text { cymene })_{2} \mathrm{Ru}_{3} \mathrm{~S}_{2}(\mathrm{NCMe})_{3}\right]^{2+}$ with sulfide sources efficiently affords the cluster of clusters [(cymene) ${ }_{6} \mathrm{Ru}_{9} \mathrm{~S}_{8}$ ] $\left(\mathrm{PF}_{6}\right)_{2}$. The synthesis is subject to coformation of [(cymene) ${ }_{4} \mathrm{Ru}_{5} \mathrm{~S}_{4}$ ] $\left(\mathrm{PF}_{6}\right)_{2}$, which arises via the reaction of $\left[(c y m e n e)_{2} \mathrm{Ru}_{3} \mathrm{~S}_{2}(\mathrm{NCMe})_{3}\right]\left(\mathrm{PF}_{6}\right)_{2}$ and [(cymene) $\left.{ }_{6} \mathrm{Ru}_{9} \mathrm{~S}_{8}\right]\left(\mathrm{PF}_{6}\right)_{2}$. Crystal lographic analysis demonstrates that [(cymene) ${ }_{6} \mathrm{Ru}_{9} \mathrm{~S}_{8}$ ] $\left(\mathrm{PF}_{6}\right)_{2}$ features three [(cymene) $\left.)_{2} \mathrm{Ru}_{3} \mathrm{~S}_{2}\right]^{2+}$ units linked through a pair of $\mu_{3}-\mathrm{S}$ ligands.

## Introduction

Sulfides derived from (cymene)Ru2+ represent an easily accessed family of clusters that display rich redox and ligand substitution. ${ }^{1,2}$ We have previously described the photoreactivity of MeCN solutions of [(cymene) $3^{-}$ $\left.\mathrm{Ru}_{3} \mathrm{~S}_{2}\right]^{2+}$, which allows the installation of a variety of donor ligands in place of one labilizable cymene, the intermediate being $\left[(\text { cymene })_{2} \mathrm{Ru}_{3} \mathrm{~S}_{2}(\mathrm{NCMe})_{3}\right]^{2+}$ (Scheme 1). ${ }^{3,4}$ In this report, we extend this reaction to include sulfide as the Lewis base.

In the present context, the behavior of [(cymene) $3^{-}$ $\left.\mathrm{Ru}_{3} \mathrm{~S}_{2}\right]^{2+}$ can be described using an analogy between arene ligands and the cluster fragment (arene) ${ }_{2} \mathrm{Ru}_{2} \mathrm{~S}_{2}$, both of which can be considered $6 \mathrm{e} \pi$-ligands. Thus, $\left[(\text { arene })_{3} \mathrm{Ru}_{3} \mathrm{~S}_{2}\right]^{2+}$ can be viewed as the sandwich complex of 12 e [Ru(arene) $]^{2+}$ with the metallo ligand $\eta^{4-}$ [(arene) $)_{2} \mathrm{Ru}_{2} \mathrm{~S}_{2}$ ]. By extension, this analogy suggests that the three cymene ligands in the parent [(cymene) $3^{-}$ $\left.\mathrm{Ru}_{3} \mathrm{~S}_{2}\right]^{2+}$ should be replaceable by [(arene) $\mathrm{Ru}_{2} \mathrm{~S}_{2}$ ] fragments, thereby giving rise to $\left\{\left[(\text { arene })_{2} R u_{2} S_{2}\right]_{3} R u_{3} S_{2}\right\}^{2+}$. A pathway to achieve this cluster condensation is provided by the photolabilization reaction described above (Scheme 1).

Dendridic clusters ${ }^{5,6}$ derived via such condensations would be unusual and interesting. Extended Ru-S species in particular are potentially relevant to catalysis, because Ru-S phases are particularly active catalysts for hydrodesulfurization (HDS), more so than typical

[^0]

Mo-Co-S systems currently used industrially. 7,8 Only one Ru-S phase is known: pyrite-like $\mathrm{RuS}_{2}$.

## Results and Discussion

[(cymene) $\left.\mathbf{6}^{\mathbf{R}} \mathbf{u}_{9} \mathrm{~S}_{8}\right]^{\mathbf{2 +}}$. A solution of [(cymene) ${ }_{2} \mathrm{Ru}_{3} \mathrm{~S}_{2^{-}}$ $\left(\mathrm{NCMe}_{3}\right]^{2+}$, generated by photolysis of [(cymene) $3^{-}$ $\left.\mathrm{Ru}_{3} \mathrm{~S}_{2}\right]^{2+}$, was found to react with 1.2 equiv of $\mathrm{Na}_{2} \mathrm{~S} \cdot$ $9 \mathrm{H}_{2} \mathrm{O}$ to produce a $98 \%$ yield of [(cymene) ${ }_{6} \mathrm{Ru}_{9} \mathrm{~S}_{8}$ ] $\left(\mathrm{PF}_{6}\right)_{2}$ ( $\mathbf{R} \mathbf{u}_{\mathbf{9}} \mathbf{S}_{\mathbf{8}}\left(\mathrm{PF}_{6}\right)_{2}$; Scheme 2). The ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{R u} \mathbf{u}_{\mathbf{9}} \mathbf{S}^{2+}$ showed that the cymeneligands are equivalent. The formula for $\mathbf{R u} \mathbf{u}_{\mathbf{9}}{ }^{2+}$ was also confirmed by ESIMS with $\mathrm{M}^{2+}$ at $\mathrm{m} / \mathrm{z}$ 986.3. X-ray crystallographic analysis showed that $\mathbf{R u} \mathbf{u}_{9} \mathbf{S}_{8}{ }^{2+}$ consists of three $\mathrm{Ru}_{3} \mathrm{~S}_{2}$ subclusters sharing a common $\mathrm{Ru}_{3} \mathrm{~S}_{2}$ core (Figure 1). The inner $\mathrm{Ru}_{3} \mathrm{~S}_{2}$ cluster closely resembles that in [(cymene) ${ }_{3} \mathrm{Ru}_{3} \mathrm{~S}_{2}$ ] $\left(\mathrm{PF}_{6}\right)_{2}$ with regard to the $\mathrm{Ru}-\mathrm{Ru}$ and $R u-S$ bond lengths of 2.78 and $2.29 \AA$, respectively. The three outer $R u_{3} \mathrm{~S}_{2}$ clusters are similar to each other but differ from the inner core, with Ru-Ru bonds averaging $2.74 \AA$ A. In [(cymene) $\left.{ }_{4} \mathrm{Ru}_{5} \mathrm{~S}_{4}\right]\left(\mathrm{PF}_{6}\right)_{2}\left(\left[\mathbf{R u}_{5} \mathbf{S}_{\mathbf{4}}\right]\left(\mathrm{PF}_{6}\right)_{2}\right)$ the $\mathrm{Ru}_{3}$ planes are related by $54.8^{\circ}$ vs the angles of $55.8^{\circ}$ for $\mathbf{R u}_{9} \mathbf{S}_{8}{ }^{2+}$, suggesting a common electronic effect.

Extended photolysis of solutions of $\mathbf{R u} \mathbf{u g S}_{8}{ }^{2+}$ in the presence of $\mathrm{Na}_{2} \mathrm{~S} \cdot 9 \mathrm{H}_{2} \mathrm{O}$ resulted in no further condensation to higher nuclearity Ru/S clusters; the photolysis sol utions remained homogeneous, and free cymene was not observed. Solutions of $\mathbf{R} \mathbf{u}_{\mathbf{9}} \mathbf{S}_{\mathbf{8}}{ }^{2+}$ slowly decompose to give some $\mathbf{R} \mathbf{u}_{5} \mathbf{S}_{4}{ }^{2+}$ (see below).
$\left[(c y m e n e){ }_{4} \mathbf{R} \mathbf{u}_{5} \mathbf{S}_{\mathbf{4}}\right]^{\mathbf{2 +}}$. With fewer equivalents of sulfide, the main product is $\mathbf{R} \mathbf{u}_{5} \mathbf{S}_{\mathbf{4}}{ }^{2+}$, which had been previously isolated in trace amounts from the prolonged photolysis of $\mathbf{R} \mathbf{u}_{3} \mathbf{S}_{\mathbf{2}}{ }^{2+} .{ }^{3}$ The use of NaSH often leads to cleaner syntheses ( $55 \%$ yield). The formation of $\mathbf{R} \mathbf{u}_{5} \mathbf{S}_{4}{ }^{2+}$ appears to proceed via the initial formation of $\mathbf{R} \mathbf{u}_{\mathbf{9}} \mathbf{S}_{\mathbf{8}}{ }^{2+}$,

[^1]
which is attacked by the unreacted [(cymene) $)_{2} \mathrm{Ru}_{3} \mathrm{~S}_{2^{-}}$ $\left.(\mathrm{NCMe})_{3}\right]^{2+}$. Consistent with this hypothesis, addition of 2 equiv of $\left[(c y m e n e)_{2} \mathrm{Ru}_{3} \mathrm{~S}_{2}(\mathrm{NCMe})_{3}\right]^{2+}$ to $\mathbf{R u}_{9} \mathbf{S}_{8}{ }^{2+}$ resulted in a nearly quantitative conversion to $\mathbf{R} \mathbf{u}_{5} \mathbf{S}_{\mathbf{4}}{ }^{2+}$ (90\%). To prevent the formation of $\mathbf{R u}_{5} \mathbf{S}_{4}{ }^{2+}$ excess $\mathrm{Na}_{2} \mathrm{~S}$ $9 \mathrm{H}_{2} \mathrm{O}$ (1.2 equiv) is needed-if the exact stoichiometry ( 0.66 equiv) of $\mathrm{Na}_{2} \mathrm{~S} \cdot 9 \mathrm{H}_{2} \mathrm{O}$ is added, a substantial amount of $\mathbf{R} \mathbf{u}_{\mathbf{5}} \mathbf{S}_{\mathbf{4}}{ }^{2+}$ (40\%) is formed with $\mathbf{R} \mathbf{u}_{\mathbf{9}} \mathbf{S}_{\mathbf{8}}{ }^{2+}$.

In an attempt to probe the cluster condensation pathway, we treated $\left[(c y m e n e)_{2} \mathrm{Ru}_{3} \mathrm{~S}_{2}(\mathrm{NCMe})_{3}\right]^{2+}$ with varying amounts of $\mathrm{PPh}_{4} \mathrm{TeH} .{ }^{9} \mathrm{ESI}-\mathrm{MS}$ analysis showed that these reactions produced mainly $\mathbf{R} \mathbf{u}_{5} \mathbf{S}_{4}{ }^{2+}$, not Tecontaining products such as $\mathbf{R} \mathbf{u}_{5} \mathbf{S}_{\mathbf{4 - x}} \mathbf{T} \mathbf{e}_{\mathbf{x}}{ }^{2+}$. With 1.1 equiv of $\mathrm{PPh}_{4} \mathrm{TeH}$, a species of unknown structure, $\left[R u_{6} \text { (cymene) }{ }_{4} \mathrm{~S}_{2} \mathrm{Te}_{2}\right]^{2+}$ (m/z 763), was a major product, as indicated by ESI-MS.

## Summary

The present work extends the range of ligands that react with $\left[(c y m e n e)_{2} \mathrm{Ru}_{3} \mathrm{~S}_{2}(\mathrm{NCMe})_{3}\right]^{2+}$. The condensation reactions are proposed to proceed via the sulfido-

Figure 1. Molecular structure of [(cymene) $\left.{ }_{6} \mathrm{Ru}_{9} \mathrm{~S}_{8}\right]\left(\mathrm{PF}_{6}\right)_{2}$ showing the atom-labeling scheme. Thermal ellipsoids are drawn at the 50\% level.
bridged dimer of clusters [(cymene) ${ }_{2} \mathrm{~S}_{2} \mathrm{Ru}_{3} \mathrm{~S}_{2} \mathrm{Ru}_{3} \mathrm{~S}_{2^{-}}$ (cymene) $)_{2}$ ] or MeCN adducts thereof. Related unsaturated sulfido and thiolato species include Cp* $2 R_{2} \mathrm{~S}_{2}$ and $\left(\mathrm{C}_{6} \mathrm{Me}_{6}\right) \mathrm{Ru}(\mathrm{SAr})_{2} .{ }^{10,11} \mathrm{Ru}_{3} \mathrm{~S}_{2} \mathrm{Ru}_{3}$ species with a square $\mathrm{Ru}_{2} \mathrm{~S}_{2}$ core would be suited for condensation with $\left[(c y m e n e)_{2} \mathrm{Ru}_{3} \mathrm{~S}_{2}(\mathrm{NCMe})_{3}\right]^{2+}$, yiel ding $\mathbf{R u g} \mathbf{S}_{8}{ }^{2+}$. We were unable to convert $\mathbf{R u} \mathbf{u}_{\mathbf{9}} \mathbf{S}^{2+}$ or $\mathbf{R} \mathbf{u}_{\mathbf{5}} \mathbf{S}_{\mathbf{4}}{ }^{2+}$ into larger clusters because their arene ligands are nonlabile. The effect of different arene ligands merits further investigation.

## Materials and Methods

General Considerations. Standard Schlenk techniques were used in all syntheses. An immersion reactor ( 150 mL ) with a water-cool ed quartz sheath was used for photolysis. The UV light source was a medium-pressure mercury-vapor Iamp (Hanovia, 200 W ). ${ }^{1} \mathrm{H}$ NMR spectra were acquired on Unity Varian 400 and 500 spectrometers. Elemental analyses were determined by the Microanalytical Laboratory at the School of Chemical Sciences.
[(cymene) $\left.\mathbf{6}_{\mathbf{R}} \mathbf{u}_{9} \mathbf{S}_{8}\right]\left(\mathrm{PF}_{6}\right)_{\mathbf{2}}\left(\left[\mathrm{Ru}_{9} \mathbf{S}_{8}\right]\left(\mathrm{PF}_{6}\right)_{2}\right)$. A solution of 628 $\mathrm{mg}(0.592 \mathrm{mmol})$ of [(cymene) ${ }_{3} \mathrm{Ru}_{3} \mathrm{~S}_{2}$ ] $\left(\mathrm{PF}_{6}\right)_{2}$ in 60 mL of MeCN was photolyzed for 1 h before being treated dropwise with a solution of $176 \mathrm{mg}(0.733 \mathrm{mmol})$ of $\mathrm{Na}_{2} \mathrm{~S} \cdot 9 \mathrm{H}_{2} \mathrm{O}$ (Aldrich) in 15 mL of $\mathrm{H}_{2} \mathrm{O}$. After 1 h , the resulting black solution was evaporated to dryness. The solid was extracted into 40 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, which was also evaporated to leave a solid. The product was re-extracted into 10 mL of THF and reprecipitated with 120 mL of hexane. Yield: 439 mg (98\%). ${ }^{1} \mathrm{H}$ NMR (MeCN): 1.27 (d, 6H), 2.22 (s, 3H), 2.56 (sept, 1H), 5.47 (q, $4 \mathrm{H})$. ESI-MS: m/z 986.6 ([M $\left.{ }^{2+}\right]$ ). Anal. Calcd (found) for $\mathrm{C}_{60} \mathrm{H}_{84} \mathrm{~F}_{12} \mathrm{P}_{2} \mathrm{Ru}_{9} \mathrm{~S}_{8}: \mathrm{C}, 31.87$ (31.73); H, 3.74 (4.01); N, 0 (0.19). Crystals for X-ray diffraction grew over the course of 2 weeks by vapor diffusion of $\mathrm{Et}_{2} \mathrm{O}$ into a solution of 25 mg of [ $\mathbf{R u}_{\mathbf{9}} \mathbf{S}_{8}$ ] $\left(\mathrm{PF}_{6}\right)_{2}$ in 3 mL of MeCN .
[(cymene) $\left.\mathbf{4}^{\mathbf{R}} \mathbf{u}_{5} \mathbf{S}_{\mathbf{4}}\right]\left(\mathrm{PF}_{6}\right)_{2}\left(\left[\mathrm{Ru}_{5} \mathbf{S}_{4}\right]\left(\mathrm{PF}_{6}\right)_{2}\right)$. A solution of 213 $\mathrm{mg}(0.201 \mathrm{mmol})$ of $\left[(c y m e n e)_{3} R u_{3} \mathrm{~S}_{2}\right]\left(\mathrm{PF}_{6}\right)_{2}{ }^{1}$ in 45 mL of MeCN was irradiated with UV light with stirring for 1 h . The resulting solution was treated dropwise with a solution of 6

[^2]

mg ( 0.107 mmol ) of NaSH in 5 mL of $\mathrm{H}_{2} \mathrm{O}$. The reaction sol ution was evaporated to dryness, and the solid residue was rinsed with 3 mL of THF and 10 mL of $\mathrm{H}_{2} \mathrm{O}$. The product was extracted into ca. 5 mL of acetone and reprecipitated with 80 mL of $\mathrm{Et}_{2} \mathrm{O}$ to give a red-brown powder, which was filtered and washed with $\mathrm{Et}_{2} \mathrm{O}$. Yield: 84 mg ( $55 \%$ ). ${ }^{1} \mathrm{H}$ NMR (MeCN): 1.27 (d, 6H), 2.23 (s, 3H), 2.55 (sept, 1H), 5.65 (q, $4 \mathrm{H})$. ESI-MS: m/z 585 ([ $\left.\mathrm{M}^{2+}\right]$ ). These data match those previously reported. ${ }^{3}$

Crystallography. Crystals were mounted on thin glass fibers using Paratone-N oil (Exxon) before being transferred

to a Siemens Platform/CCD automated diffractometer for data collection. Data processing was performed with SAINT PLUS, version 6.22. Structures were solved using direct methods and refined using full-matrix least squares on $F^{2}$ using the Bruker program SHELXTL, version 6.10. Hydrogen atoms were fixed in idealized positions with thermal parameters 1.5 times those of the attached carbon atoms. The data were corrected for absorption on the basis of $\psi$ scans. Specific details for each crystal are given in Table 1; selected bond distances and angles are given in Table 2. Full crystallographic details have been deposited with the Cambridge Crystal lographic Data Center as Supplementary Publication No. CCDC-239367.
